Data types

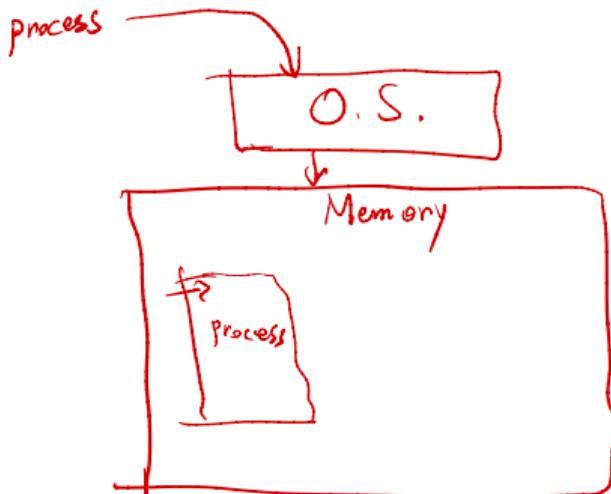

- Data type indicates the category of data and its properties (including the size, permitted operations, etc.).
- Different data types:
 - ▶ Built-in types : elementary data types in programming lang (int, char, float ...)
 - ▶ Arrays : collection of data with identical type.
 - ▶ Struct and class : collection of data (methods) with possibly different types.
 - ▶ Data structures : User-defined collection of data and its operations.

Memory management

- How different types of data are stored and manipulated in memory?
- The role of operating system : managing all the resources
(memory, etc.)
- Different parts of program/process: code, data, stack, heap

Memory management:

- Segmentation
- Paging

Memory management: segmentation

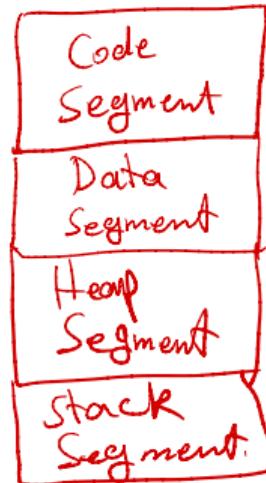

```
int main() {  
    int x;  
    char c;  
    cin >> x >> c;  
    cout << x << c;  
    return (0);  
}
```

Compile

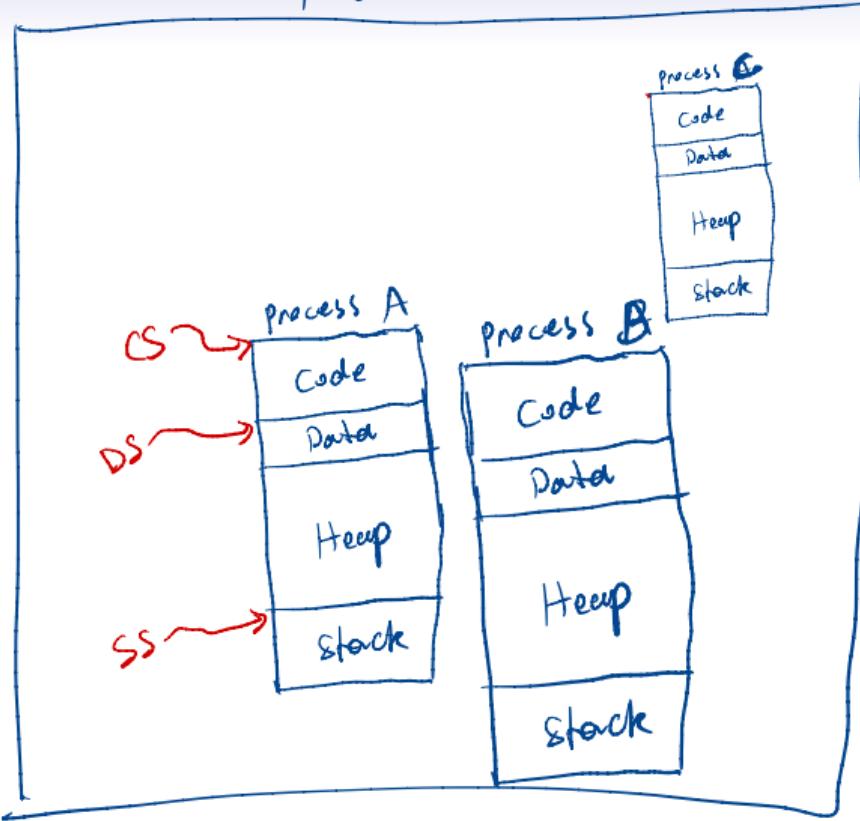

Machine
code.
(obj)

File system
main.exe
file

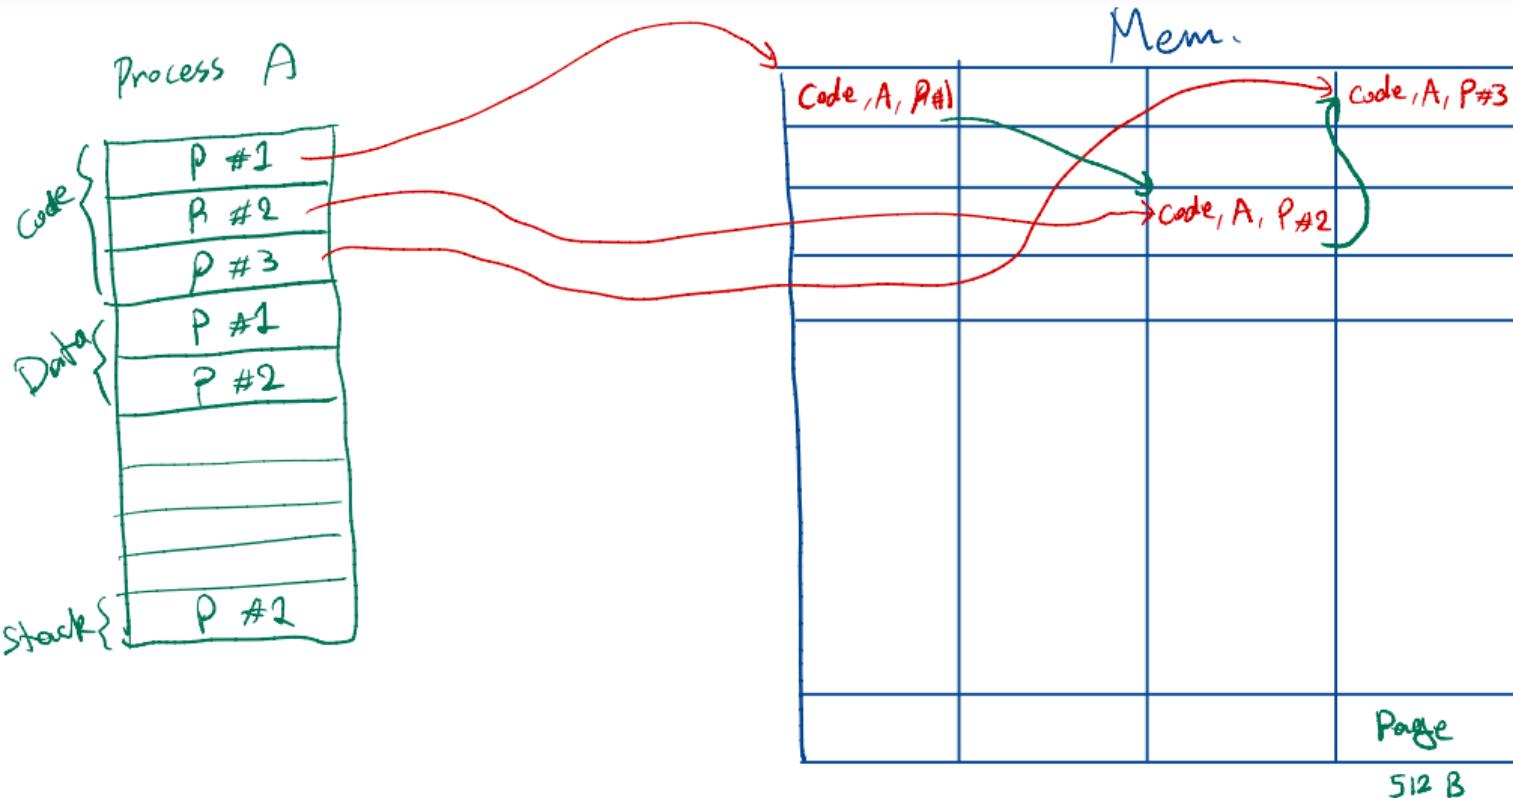

Process main

Mem.

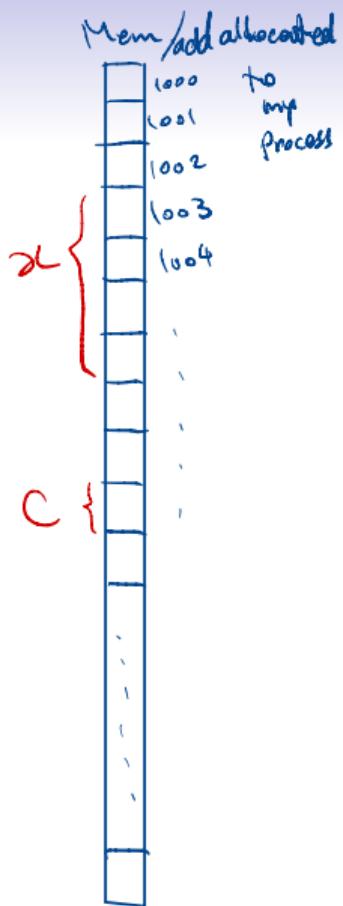

Memory management: paging

Variables

- A place-holder in memory for storing data.
- Variables' attributes:
 - ▶ The number of allocated memory bytes
 - ▶ The location of the allocated memory
 - ▶ The defined/permitted operations on it
 - ▶ Type casting: convert one type to another

Pointers

- A place-holder in memory for storing memory address!
- Can be used to access the stored data.

```
int x=5;
```

```
int *P;
```

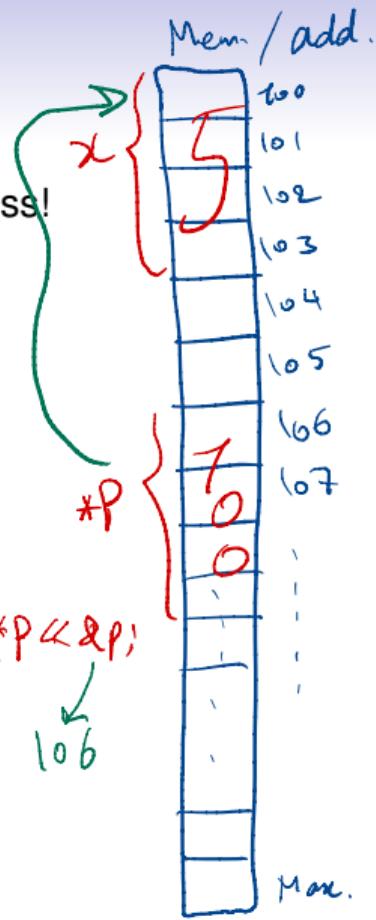

```
P=&x;
```

```
cout << x << *P << P;
```

5 5 106

```
cout << P;
```

100

`type * p;`

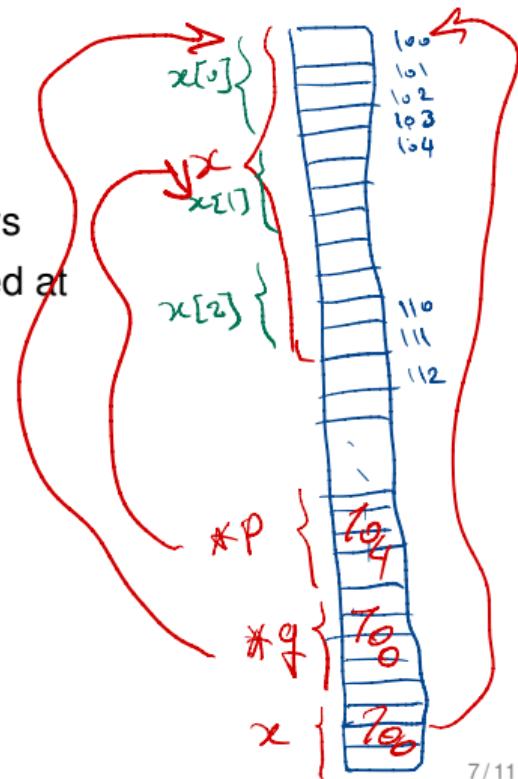

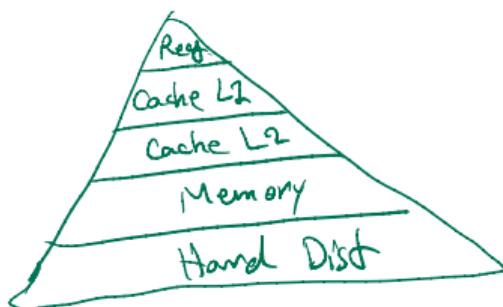

$p++ \Rightarrow p = p + \text{size of}(type)$

Arrays

`int x[3] = {1, 5, 7};`

`int *p = &x[1]; p++`
~~`int q = x;`~~

- Contiguous area of memory consists of equal-size elements indexed by contiguous integers
- Random access (constant time)
- Fixed size (static memory allocation)
- Consecutive memory bytes are allocated to arrays
- Number of elements in an array could be specified at
 - ▶ compile time (static memory allocation)
 - ▶ run time (dynamic memory allocation)

Multi-dimensional arrays

A

A[0,0]	A[0,1]	A[0,2]	A[0,3]
A[1,0]	A[1,1]	- - -	
-	-	-	A[2,3]

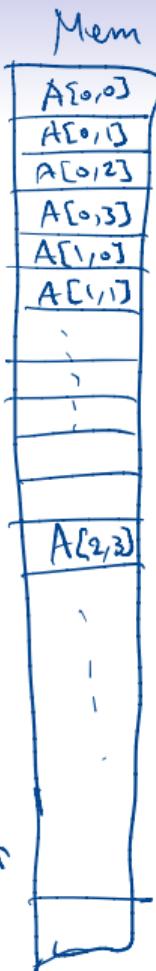

rows $m \times n$ columns

row-major

$k = \text{index of element } [i,j] \text{ in mem}$

$$= A + (i * n) * \text{elementSize} + j * \text{elementSize.}$$

Dynamic memory allocation

- Should be asked from the **operating system** to do the memory allocation at run-time.
- **Pointers** are usually required.

int *p ; could be specified at run-time.

p = (int *) malloc (n * sizeof (int)) ;

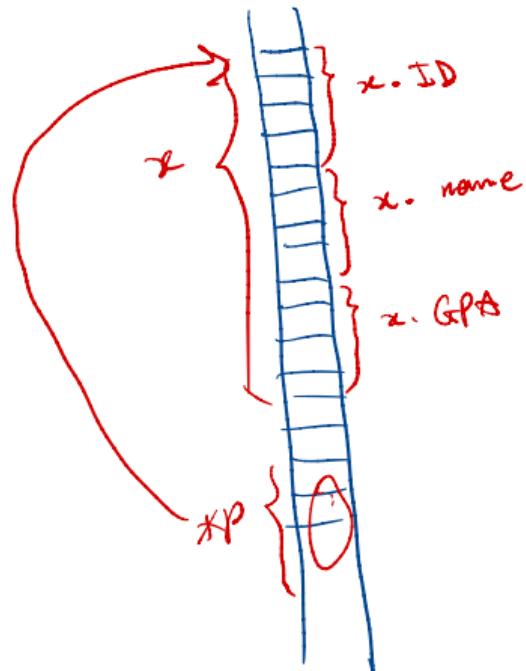

↓
memory allocation.

→ points to an array of type 'int' with n elements.

Struct and Class

- To define a new type containing different types of data (fields).
- User-defined type.

```
struct Student {  
    int ID;      4 bytes  
    char * name; 4 bytes  
    float GPA;   4 bytes  
    :  
}  
  
student x;  
struct *p = &x;
```

Abstract Data Type (ADT)

Concerns **what** is getting done not **how** it is getting done.

Definition

A class of objects whose logical behavior is defined by a set of values and a set of operations.

-Constructors -

-Transformers -

change/modify the
state of ADT

- Observers:

allow read-only
access to the state
of ADT

- Iterators:

allow sequential access to the elements in ADT.

- Destructors,
clear the state
of ADT.
